

storing user data

plaintext field hashed/encrypted  
with user secret for obfuscation

place relevant data  
at obfuscated field

field

obfuscated field

hash of plaintext  
data, IPFS URL to  
encrypted data

## 2FA identity verification

submit 2FA token/biometric  
parameters/secret through third  
party API or identity server

update identity parameters'  
timestamp in smart contract,  
transfer vera coin to oracle

generating certificates and on-boarding proof of  
certificate knowledge to smart contract

submit request for a number of  
signing certificates to oracle CA

onboard verifier certificate  
proof as signature/hash

return nonce and certificates  
to verifier

optionally, submit request for a  
user secret/certificate

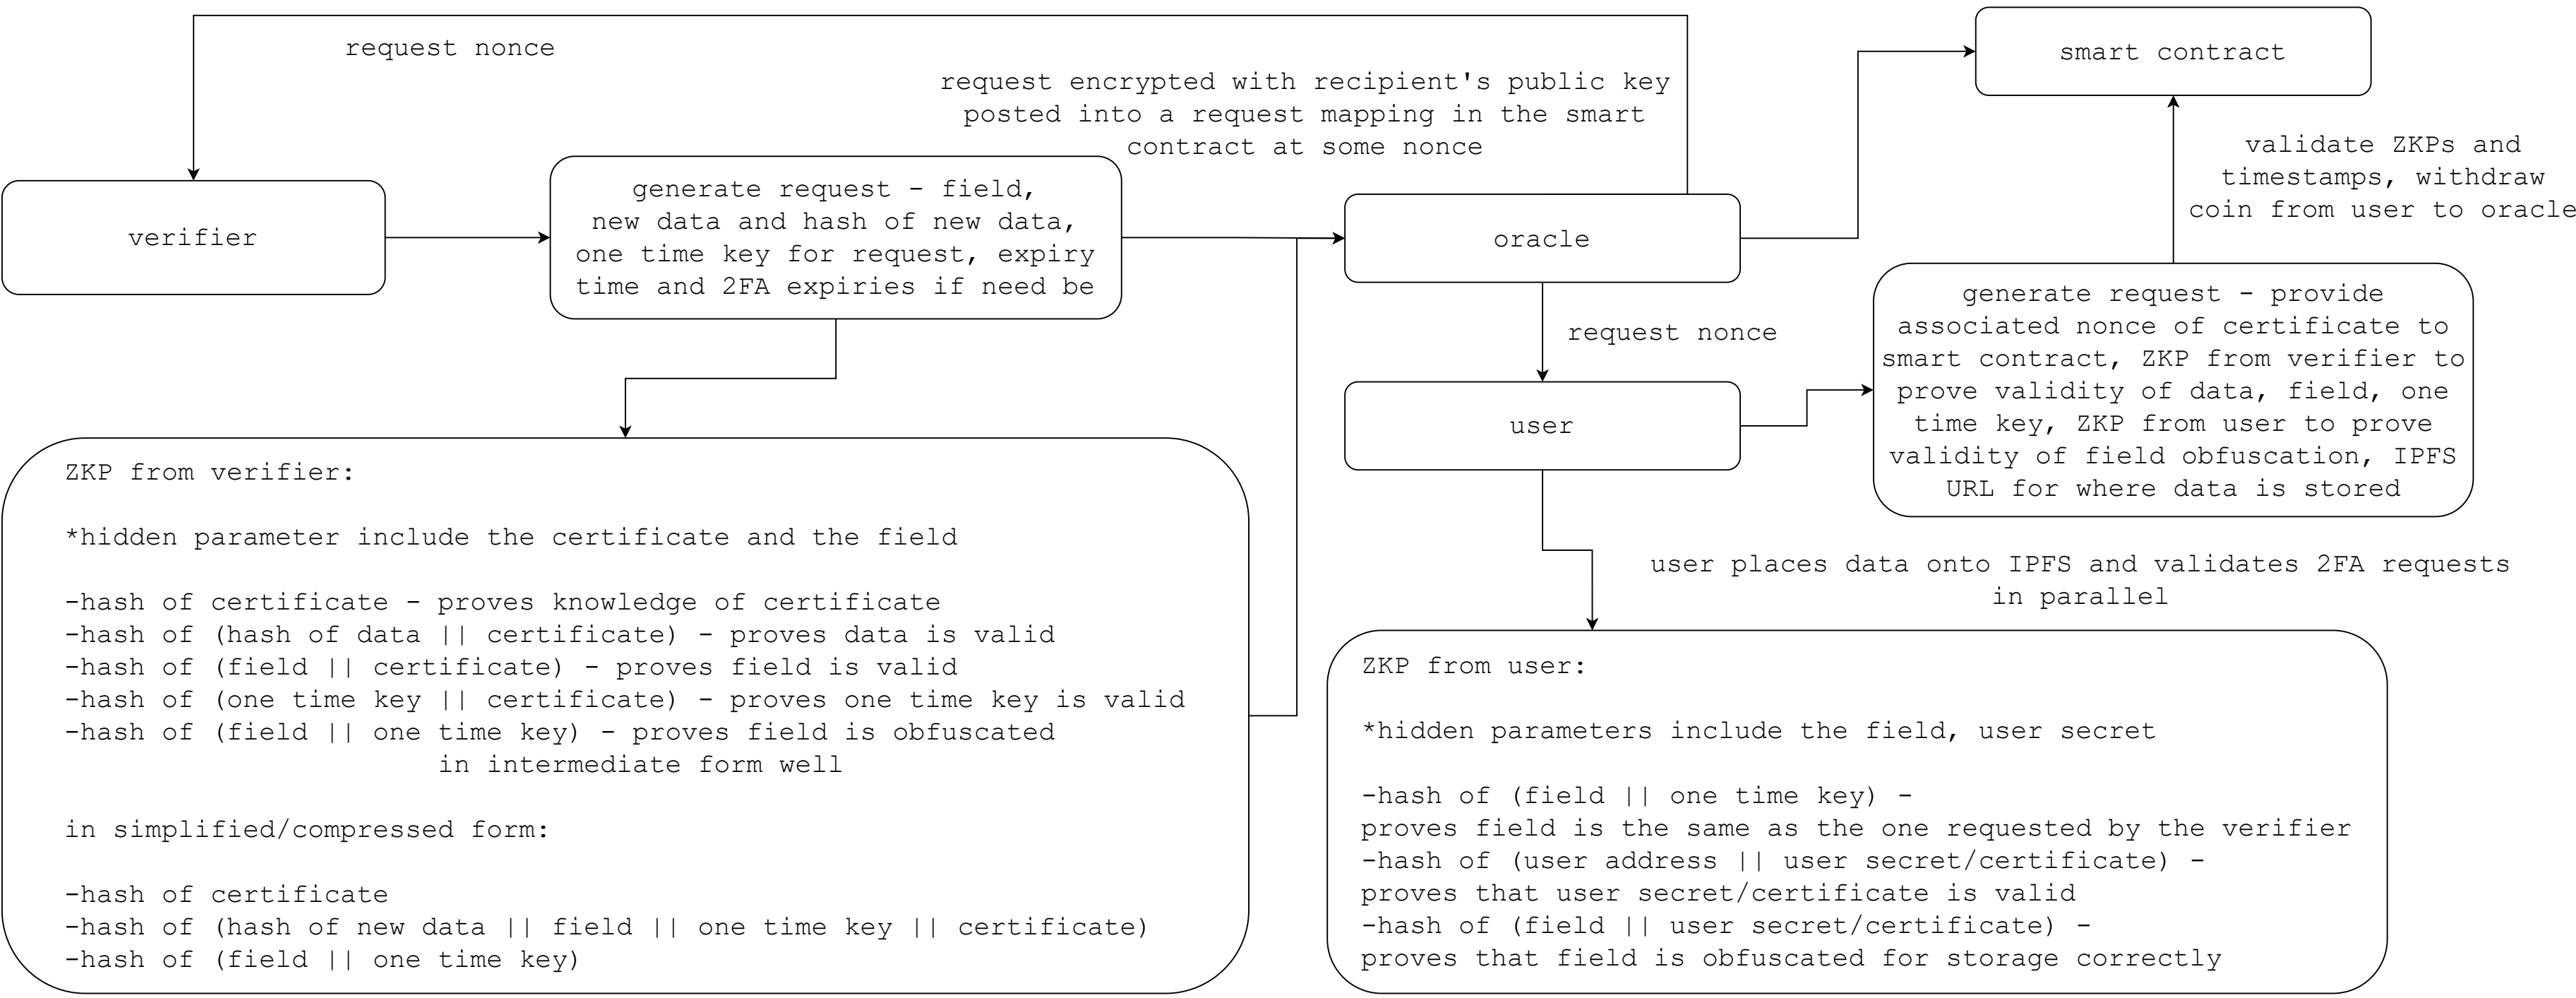

onboard user secret  
proof as signature/hash

\*to encourage certificate rotation and to limit the number of requests to oracles verifiers can make with given certificates, they have an associated limited number of times they can be used, additionally, oracles cannot be paid outright (to remove link between transaction senders and receivers) by verifiers - "request abuse" can be mitigated with this disincentive - an off-chain oracle CA, initially, a vera server, for example, can be paid via an SaaS provision or an alternative coin to vera's

submitting requests to onboard new data

submitting requests to prove ownership of data
